

Lecture 10: Type Checking II

Yu Feng
Winter 2021

Outline

- We will talk about types in λ^+

Motivation

- When writing programs, everything is great as long as the program works.
- Unfortunately, this is usually not the case
- Programs crash, don't compute what we want them to compute, etc.
- This is arguably the **biggest problem** software faces today

Software correctness

- Problem: Rice's theorem. Any non-trivial property about a Turing machine is undecidable
- This means that we can never give an algorithm, that for all programs can decide if this program has an error on some inputs.
- What can we do?

Big idea

- Big Idea: Just because we cannot prove something about the original program does not mean we cannot prove something about an *abstraction of the program*.
- Strategy: In addition to the operational semantics, we will also define *abstract semantics* that will overapproximate the states a program is in.
- Example: In λ^+ , the operational semantics compute a concrete integer or list, while our abstract semantics only compute the if the result is of kind integer or list.

Abstraction

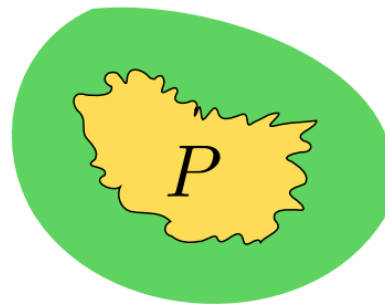

- Of course, any abstraction will be less precise than the program
- One popular abstraction: types
- Let's assume we have types Int and List
- Example: let $x = 10$ in x
- Operational semantics yield concrete value 10
- Abstract semantics that only differentiate the kind (or type) of the expression yield: Integer

Abstraction

- But we don't just want any abstraction, we need abstractions that *overapproximate* the result of the concrete program
- Recall the example: let $x = 10$ in x
- Abstract value *Integer* overapproximates 10 since 10 is a kind of integer
- On the other hand, abstract value *List* does not overapproximate 10.

Soundness

- The reason we only care about sound abstract semantics is the following:
- Theorem: If some abstract semantics are sound and an expression is of abstract value x , then its concrete value y is always part of the abstract value x .

- Why is this useful?
- This means that if a program has no error in the abstract semantics, it is guaranteed not to have an error in the concrete semantics.
- ASTREE tools: <http://www.astree.ens.fr/>

Types

- In this class, we will focus on one kind of abstraction: types
- This means abstract values are the types in the language
- What is a type? An abstract value representing an (usually) infinite set of concrete values
- Question: For proving what kind of properties are types as abstract values useful?
- Answer: To avoid run-time type errors!

Adding types to λ^+

- The original syntax of λ^+

$$\begin{array}{l} e ::= e_1 + e_2 \\ \quad | \text{Int} \quad | \text{let } x = e_1 \text{ in } e_2 \\ \quad | \text{if } e_1 \text{ then } e_2 \text{ else } e_3 \\ \quad | \lambda x.e \quad | e_1 e_2 \\ \quad | !e \quad | \#e \quad | e_1 @ e_2 \end{array}$$

- Adding type to λ^+

$$T ::= T \rightarrow T \mid \text{Int} \mid \text{List}[T]$$

Typing rules for arithmetic

$$\frac{}{\Gamma \vdash i : \text{Int}} \text{T-INT}$$

Any integer constant i is of type **integer**

$$\frac{\Gamma \vdash e_1 : \text{Int} \quad \Gamma \vdash e_2 : \text{Int} \quad \square \in \{+, -, *\}}{\Gamma \vdash e_1 \square e_2 : \text{Int}} \text{T-ARITH}$$

if e_1 and e_2 are both integers, then
 $e_1 \square e_2$ will also be integer

Typing rules for if-else

$$\frac{\Gamma \vdash e_1 : \text{Int} \quad \Gamma \vdash e_2 : T \quad \Gamma \vdash e_3 : T}{\Gamma \vdash \text{if } e_1 \text{ then } e_2 \text{ else } e_3 : T} \text{IF}$$

if e_1 is of type integer, both e_2 and e_3 have the same type T , then the whole if-else expression is of type T

Typing rules for lambda

$$\frac{\Gamma, x : T_1 \vdash e : T_2}{\Gamma \vdash \text{lambda } x : T_1. e : T_1 \rightarrow T_2} \text{ T-LAMBDA}$$

If x is of type T_1 and e is of type T_2 ,
then the lambda expression has type $T_1 \rightarrow T_2$

$$\frac{\Gamma \vdash e_1 : T_1 \rightarrow T_2 \quad \Gamma \vdash e_2 : T_1}{\Gamma \vdash (e_1 \ e_2) : T_2} \text{ T-APP}$$

if e_1 has type $T_1 \rightarrow T_2$, and e_2 has type T_1 ,
then lambda app return a value of type T_2

Typing rules for let-binding

$$\frac{x : T \in \Gamma}{\Gamma \vdash x : T} \text{ T-VAR}$$

If the type of x is T in the current type environment, then x is of type T

$$\frac{\Gamma, x : T_1 \vdash e_1 : T_1 \quad \Gamma, x : T_1 \vdash e_2 : T_2}{\Gamma \vdash \text{let } x = e_1 \text{ in } e_2 : T_2} \text{ T-LET}$$

if x and e_1 are of type T_1 and e_2 is of type T_2 ,
then the whole expression has type T_2

Typing rules for list

$$\frac{}{\Gamma \vdash \text{Nil} : \text{List}[T]} \text{T-NIL}$$

An empty list is a list

$$\frac{\Gamma \vdash e_1 : T \quad \Gamma \vdash e_2 : \text{List}[T]}{\Gamma \vdash e_1 @ e_2 : \text{List}[T]} \text{T-CONS}$$

if e_1 is of type T and e_2 is of type $\text{List}[T]$,
then $e_1 @ e_2$ is of type $\text{List}[T]$

$$\frac{\Gamma \vdash e : \text{List}[T]}{\Gamma \vdash !e : T} \text{T-HEAD}$$

if e contains a list of elements of type T ,
then $!e$ is of type T

$$\frac{\Gamma \vdash e : \text{List}[T]}{\Gamma \vdash \#e : \text{List}[T]} \text{T-TAIL}$$

if e contains a list of elements of type T ,
then $\#e$ is of type $\text{List}[T]$

Typing checking by example

$[1,2] : \text{List}[\text{int}]$

$\lambda x:\text{int}. x+2 : \text{int} \rightarrow \text{int}$

$y : \text{List}[\text{int}]$

$\lambda x:\text{int}. x+2 \ y$

wrong!

$\text{let } y = [1,2] \text{ in } \lambda x:\text{int}. x+2 \ y$

$\underbrace{[1,2]}_{e_1} \quad \underbrace{\lambda x:\text{int}. x+2}_{e_2} \ y$

TODOs by next lecture

- HW3 is due today
- HW4 is out. Please start ASAP!
